*)

(* Structural equality *)

(* Sometimes, it is also handy to be able to use structural equality.
   This equality is mapped to the build-in equality of backends. This equality
   differs significantly for each backend. For example, OCaml can't check equality
   of function types, whereas HOL can.  When using structural equality, one should
   know what one is doing. The only guarentee is that is behaves like
   the native backend equality.

   A lengthy name for structural equality is used to discourage its direct use.
   It also ensures that users realise it is unsafe (e.g. OCaml can't check two functions
   for equality *)

(* ---------------------- *)

(* bounded size natural numbers, i.e. positive integers *)

(* "nat" is the old type "num". It represents natural numbers.
   These numbers might be bounded, however no checks of the boundedness are
   provided. The theorem prover backends map nat to unbounded size
   natural numbers. However, OCaml uses the type "int", which is bounded.
   Using "int" allows using many functions like "List.length" without wrappers.
   This leeds to nice readable code, but a slightly fuzzy concept what
   "nat" represents. If you want to use unbounded natural numbers, use "natural"
   instead. *)

(* ========================================================================== *)
(* Searching lists                                                            *)
(* ========================================================================== *)

(* ------------------------ *)
(* Membership test          *)
(* ------------------------ *)

(* The membership test, one of the basic list functions, is actually tricky for
   Lem, because it is tricky, which equality to use. From Lem‘s point of
   perspective, we want to use the equality provided by the equality type - class.
   This allows for example to check whether a set is in a list of sets.

   However, in order to use the equality type class, elem essentially becomes
   existential quantification over lists. For types, which implement semantic
   equality (=) with syntactic equality, this is overly complicated. In
   our theorem prover backend, we would end up with overly complicated, harder
```

```
   to read definitions and some of the automation would be harder to apply.
   Moreover, nearly all the old Lem generated code would change and require
   (hopefully minor) adaptions of proofs.

   For now, we ignore this problem and just demand, that all instances of
   the equality type class do the right thing for the theorem prover backends.
*)

11 Set

```
(*****************************************************************************)
(* A library for sets                                                        *)
(*                                                                           *)
(* It mainly follows the Haskell Set-library                                 *)
(*****************************************************************************)

(* Sets in Lem are a bit tricky. On the one hand, we want efficiently executable sets.
   OCaml and Haskell both represent sets by some kind of balancing trees. This means
   that sets are finite and an order on the element type is required.
   Such sets are constructed by simple, executable operations like inserting or
   deleting elements, union, intersection, filtering etc.

   On the other hand, we want to use sets for specifications. This leads often
   infinite sets, which are specificied in complicated, perhaps even undecidable
   ways.

   The set library in this file, chooses the first approach. It describes
   *finite* sets with an underlying order. Infinite sets should in the medium
   run be represented by a separate type. Since this would require some significant
   changes to Lem, for the moment also infinite sets are represented using this
   class. However, a run-time exception might occour when using these sets.
   This problem needs adressing in the future. *)
